A: The problem is that DDF is creating the HTML before the document is fully loaded. Try inserting `$(function() { });` into the `$(document).ready()`

section. This is relevant because in html5 pages the load event can be detected only after the whole HTML is loaded, but inside javascript tags is allready loaded. So in your case you need to detect if the whole HTML is loaded before you start calling things like getNext(), renderGames() etc.

Light and vision in water: fish photoresponses and light interference effects. Fish photoreceptors capable of detecting changes in the Earth's magnetic field have been demonstrated in several teleost species in nature. These photoreceptors are sensitive to visible wavelengths (up to 600 nm), which suggests that the eyes of fishes are responsive to light in the visible range. To examine the spectral sensitivity of fish eyes, light and vision were studied in three groups of teleost fishes from subtropical (swordtail, *Xenotoca eiseni*), temperate (rainbow trout, *Oncorhynchus mykiss*), and tropical (kuna, *Leucaspius delineatus*) environments. These include both a the typical nictitating/opercular membrane-style eye and a second type of tectum/retina-style eye containing rods and double cones. A brief measure of vision was conducted in a water tank using a computerized optomotor response paradigm. The results show that all three species have rod vision (best at 650 nm). Two of

the three groups (kuna and *X. eiseni*) also have double cone vision that is best sensitive to yellow light. The third group, *L. delineatus*, also have rods, but only double cones were effective, most sensitive to green light. A more detailed measure of vision showed that some of these species have three stages of visual discrimination. The first stage is based on light intensity, where fishes change their direction to avoid collisions with objects. The second stage is based on color, where fishes discriminate an object's color. The third stage is based on details, such as an object's size, shape, and movement. The last two stages (intensity and color discrimination) are important for survival in the environment. There were significant differences in the color discrimination and size discrimination between the three fish groups. The sensitivity of the three species to light was different, with the group from the tropical environment being the most sensitive.
