Mathematical Physics. Mitochondria are the powerhouse of a cell, catalyzing the process of ATP (adenosine triphosphate) production by oxidative phosphorylation to maintain cellular energy. Besides its role in cellular energy production, mitochondria are also responsible for generation of ROS (Reactive oxygen species), such as $O^{\cdot 2}$ and H_2O_2 , which are in turn involved in critical cellular signaling events. Mitochondria undergo bioenergetics, fission/fusion, redox cycling, and quality control to maintain their own structure and function. Any stress or defect to mitochondria results in mitochondrial dysfunction, implicated in metabolic diseases, aging and neurodegenerative diseases. Mitochondrial dysfunction is a prominent feature of several human disorders, such as Alzheimer's disease (AD), Huntington's disease, Friedreich's ataxia, Parkinson's disease (PD), diabetes, cardiomyopathy, and muscular dystrophy ([@b1-bt-25-387]; [@b6-bt-25-387]). Mitochondria-targeting drugs help reduce neurodegeneration, mitochondrial dysfunction, and also slow down the progression of AD. For instance, one of the most widely prescribed drugs for AD treatment, rivastigmine, is the only FDA (Food and Drug Administration)-approved medication for AChE (acetylcholinesterase inhibitor) ([@b4-bt-25-387]). However, many commonly used AD drugs remain unable to address several major hallmarks of AD pathology. Since pathological hallmarks of AD are primarily due to mitochondrial dysfunction, the search for therapeutic options such as mitochondrial-targeted drugs becomes an important approach to neurodegenerative disorders ([@b8-bt-25-387]). In a previously published review on mitochondrial-targeted drugs, various aspects of mitochondrial dysfunction, particularly mitochondrial targeting and function, were discussed d0c515b9f4
