The LEMAG® Premet XI with its new calibrated calypter. With the LEMAG PREMETS XL you can precisely. Q: Multithreaded application is it better to block some thread of program and wait for other threads or create separate thread pool and use different threads? For example if one thread is sending a HTTP POST request to a web server and there are many other threads that are waiting for result, should I first block the thread and then give it to a thread pool or should I create and use a new thread for each HTTP POST request? A: The answer is it depends. It's better to have an event driven architecture, where each thread responds to requests. These should be simple operations that return immediately (i.e., response contained in response stream, no need to wait for anything). Waiting for results is generally slower than getting results, and HTTP requests can take a long time (between 10 seconds to a few seconds). If your HTTP request threads finish quickly, they can quickly queue up results and then process them in the order in which they arrived. If the thread takes a long time to finish
