A: You must import photos to the image editor. When importing, the photos you're trying to remove are probably unselected, so there's no corresponding remove icon. The metabolic and genetic impact of acute and chronic dehydration in the ornate dragon lizard (*Ctenophorus ornatus*). We compared the metabolic and genetic responses of *Ctenophorus ornatus* to acute and chronic dehydration, respectively, and elucidated the mechanisms responsible for the observed differences. Following acute dehydration (dehydration for 4 h with water deprivation from 24 to 28 h), but not chronic dehydration (dehydration for 7 days with water deprivation from 24 to 32 h), body mass declined, and plasma osmolality increased. In both conditions, activities of the tissue marker enzymes L-lactate dehydrogenase, malate dehydrogenase, aspartate aminotransferase and alanine aminotransferase significantly increased. Plasma and brain ornithine

concentrations were greater in the acute dehydration group. DNA methyltransferases (DNMT1, DNMT3A, DNMT3B) mRNA expression levels were upregulated in the acute dehydration group, but hypomethylated in chronic dehydration. The results suggest that increased activities of tissue enzymes, which regulate cellular homeostasis and intracellular flux of metabolites, are associated with gene expression. Due to the loss of adaptation mechanisms in chronic dehydration, body mass and plasma osmolality increased and were accompanied by enhanced water and salt intake and loss of regulation mechanisms. Physiological mechanisms resulting in increased water and salt intake to maintain homeostasis are not activated and have lessened in chronic dehydration. These biochemical and genetic differences in acute and chronic dehydration may be associated with the differing effects on the behavior and gene expression of ornate dragon lizards. Radiation therapy and short-term palliation of small cell carcinoma of the lung. Sixty-three patients with inoperable Stage III

small cell carcinoma of the lung were entered on a new program of short-course radiotherapy. The radiation dose was 3.5 Gy per fraction (five sessions per week) to the primary tumor and involved lymph nodes in the mediastinum to total dose of 25 Gy. This treatment was generally given concurrently with aminoglycoside antibiotics. One month after treatment, most patients had obtained a response of either partial or complete disappearance of symptoms and objective disease. The response rate was 68%. The majority of patients continued to benefit from this 6d1f23a050
